Acknowledgments

This report was prepared under the general direction of **Gregory Spencer**, Chief of the Population Projections Branch. **John F. Long**, Assistant Division Chief for Population Estimates and Projections, provided overall direction. Statistical assistance was provided by **Barbara E. Brenner** and **Gloria J. Hampton**. Typing assistance was provided by **Mary Jane Slagle**. **Rosalyn M. Green** assisted with computer programming.

Frederick W. Hollmann provided professional consultation and compiled the net immigration statistics. **Paul R. Campbell** provided the AIDS research and professional consultation. **William Bell** and **Brian Monsell** of the Statistical Research Division, **Eduardo E. Arriaga** of the Center for International Research, **Martin O'Connell**, **Campbell Gibson**, **Signe Wetrogan**, **David L. Word**, **Larry Sink**, and **Karen A. Woodrow** provided professional consultation. **Arnold Goldstein**, **Nampeo R. McKenney**, **Jorge del Pinal**, and **Roderick Harrison** provided comments on the report draft.

The staff of Administrative and Publications Services Division, **Walter C. Odom**, Chief, provided publication planning, design, composition, editorial review, and printing planning and procurement. **Joan Kinikin** provided publication coordination and editing. Electronic Graphics and Design provided graphic services.

Population Projections of the United States, by Age, Sex, Race, and Hispanic Origin: 1992 to 2050

These projections are consistent with the 1990 census as enumerated.

This is the first projections report which presents data for four race groups (White; Black; American Indian, Eskimo, and Aleut; and Asian and Pacific Islander) and the Hispanic origin population. The race groups also are separated into their Hispanic and Not Hispanic components.

Many of the trends described here are substantially different from those shown in the previous projections (Current Population Reports, Nos. 995 and 1018). These differences are primarily due to the changeover to the 1990 census base and three significant changes in our assumptions: 1) Future fertility is assumed to remain near current levels; 2) Future immigration is assumed to remain near current levels; and 3) Fertility and mortality differentials by race/ethnic groups are assumed to continue their current trends. The future course of population change could be substantially different—depending on the actual trends in births, deaths, and net migration.

HIGHLIGHTS FROM THE MIDDLE SERIES

Population Size and Growth

- In the middle series, the U.S. population is projected to grow from 252 million in 1991 to 383 million in 2050, a 50 percent increase. Even so, after 2020 the U.S. would grow more slowly than ever before.
- The U.S. population is projected to reach 275 million in 2000—a growth of 25.4 million or 10.2 percent after 1990. During the 1980's the population grew 21.7 million or 9.5 percent. Only during the 1950's were more people added to the nation's population than are projected to be added during the 1990's.

Age Distribution

- During the next 20 years, the elderly population (aged 65 and older) is projected to grow more slowly than it has in many decades. From 1991 through 2005 the proportion of the population that is elderly is projected to remain virtually unchanged at about 12.7 percent. By comparison, the percent aged 65 or older rose from 11.3 percent in 1980 to 12.5 percent in 1990.
- From 2010 to 2030 the survivors of the baby boom cohort will enter the 65 and over age groups. During that period, the number of people aged 65 and older is projected to increase substantially—from 39.7 million in 2010 to 69.8 million in 2030. Over 20 percent of the population would be aged 65 and older in 2030. The average annual rate of increase for this age group during these 20 years would be 2.8 percent.
- The 45 to 54 year old age group is projected to increase the most (44 percent) from 1991 to 2000. This age group would grow from 25.7 million in 1991

to 37.1 million in 2000. This growth of 11.4 million represents one-half of the nation's expected total growth during this period.

- The primary group entering the labor force, college, and the military, (ages 18 to 21), would soon begin to grow again for the first time since peaking at 17.4 million in 1980. The numbers should continue to decline from 15.2 million in 1991 to 13.8 million in 1994, then increase to 15.7 million in 2000 and 17.8 million in 2010 (a new all-time high).
- The high school age population (ages 14 to 17), which declined 2.8 million during the 1980's, would increase from 13.4 million in 1991 to 15.7 million in 2000 and 16.9 million in 2010.
- The elementary school age population (ages 5 to 13) would increase by more than 4 million during the 1990's. It only grew by one million in the 1980's.

Race and Hispanic-Origin Distribution

- The non-Hispanic White population would slowly grow from 191 million in 1992 to 208 million in 2029, then slowly decline to 202 million in 2050.
- The non-Hispanic White share of the U.S. population would steadily fall from 75 percent in 1992 to 72 percent in 2000, 68 percent in 2010, 60 percent in 2030, and 53 percent in 2050.
- Although three-quarters of the population is non-Hispanic White in 1992, this group would contribute only 30 percent of the total population growth between 1992 and 2000, 21 percent from 2000 to 2010, and 13 percent from 2010 to 2030. This group would contribute nothing to population growth after 2030 because the non-Hispanic group would be declining in size.

- The Black population is projected to almost double from 32 million in 1992 to 62 million in 2050. After about 2005, more Blacks than non-Hispanic Whites would be added to the population each year.
- The Hispanic population would rise from 24 million in 1992 to 31 million in 2000, 39 million in 2010, 59 million in 2030, and 81 million in 2050.
- The Hispanic population would contribute 33 percent of the nation's growth from 1992 to 2000, 37 percent from 2000 to 2010, 43 percent from 2010 to 2030, and 57 percent from 2030 to 2050.
- After 1995, the Hispanic population is projected to add more people to the United States every year than would the non-Hispanic White population (or any other group).
- The Asian and Pacific Islander population is expected to continue to be the fastest growing group, rising from 9 million in 1992 to 13 million in 2000, 17 million in 2010, 29 million in 2030, and 41 million in 2050.
- The Asian and Pacific Islander population (3 percent of the total U.S. population in 1992) would account for 19 percent of the nation's growth from 1992 to 2000. Each year after 2002, the Asian and Pacific Islander population would add more people to the population of the United States than would the non-Hispanic White group.

Components of Change

- The number of births is projected to slowly decline from 4.1 million in 1991 to less than 3.9 million in 2000. Births would then begin to increase steadily, and after 2015, there would be more births every year than ever before in American history.
- Currently, about 66 percent of all births are non-Hispanic White. That percentage is expected to fall to 61 in 2000, 56 in 2010, 48 in 2030, and 42 in 2050. All other race and ethnic groups would increase their share of births.
- According to the middle series, the U.S. population in the year 2000 is projected to be 9 million (3 percent) larger than it would have been if there had been no net immigration after July 1, 1991. The equivalent figures for 2010, 2030, and 2050 are 21 million (7 percent), 49 million (14 percent), and 82 million (21 percent).

MAJOR CHANGES FROM THE LAST REPORT

The projections shown here supersede the information contained in Current Population Reports, Series P-25, No. 1018 and Series P-25, No. 995. The methodology used to generate the projections in this report is similar to that used for the earlier reports. However, the base population data and several assumptions have changed.

Population Base Changes

The projections presented in this report are based on a July 1991 estimate consistent with the 1990 census, as enumerated. The projection period starts in 1992 and runs through 2050. Unlike previous projections, this report presents the resident population instead of total population including Armed Forces overseas. Resident population is consistent with both census count numbers and the subsequent national estimates, making this a more uniform series for most users. The Armed Forces overseas are still assumed to be constant at the 1991 level throughout the projected period, and therefore can be added to each resident age group to obtain the total population including Armed Forces overseas.

The race and Hispanic origin detail are combined in a single volume and presented in more detail. Race is classified into four major groups: White; Black; American Indian, Eskimo, and Aleut (AIEA); and Asian and Pacific Islander (API). Throughout this publication, the term "American Indian" or the abbreviation "AIEA" also will be used to represent the entire race group American Indian, Eskimo, and Aleut. The term "Asian" or the abbreviation "API" will refer to the race group Asian and Pacific Islander.

Data are also shown for persons of Hispanic origin. Persons of Hispanic origin can be of any race: White, Black, American Indian, or Asian. All four of the race groups are crossed by Hispanic origin, resulting in four additional groups: non-Hispanic White; non-Hispanic Black; non-Hispanic American Indian, Eskimo, and Aleut; and non-Hispanic Asian and Pacific Islander.

Assumptions Changes

Specific component starting points and assumed ending points for this set of projections compared with the earlier projections are highlighted in table A. The following explains some of the major assumption differences since the last projection reports.

The immigration component, especially, depends on legislative policy. In the interim between the last projections report and this one, changes in immigration laws necessitated a rethinking of the immigration assumptions. The last report assumed the Immigration and Reform Act of 1986 (IRCA) would partially reduce undocumented immigration. In fact, there is no evidence of any reduction in the undocumented movement. In addition, the Immigration Act of 1990 allows more immigration. For these reasons, the future immigration assumptions for undocumented, legal and refugee immigrants were increased.

Likewise, the fertility assumptions also have changed since the last report. First, the level of the fertility assumption is higher. The last report assumed a decrease

Table A. Comparison of Principal Fertility, Mortality, and Net Immigration Assumptions Between Old Projections and New Projections

(Middle series)

Subject	Old projection		New projection	
	1987	2050	1992	2050

NA Not available.

¹American Indian represents American Indian, Eskimo, and Aleut.

²American Indian and Asian figures were not available separately. Together, their 1987 and 2050 values for fertility were 2,147 and 1,800, for life expectancy were the same as White, and for net immigration were 176,000 and 173,000.

³Asian represents Asian and Pacific Islander.

⁴Persons of Hispanic origin may be of any race.

in the total fertility rate to 1.8 births per woman. However, since the late 1980's, after a relatively stable 15-year trend of low fertility, there has been a dramatic rise in total fertility levels to almost 2.1 births per woman. Second, convergence of fertility among race and ethnic groups is no longer assumed. Historical data show that though fertility rates for different groups do experience similar effects, there is little evidence to assume that their fertility rates will eventually converge. Third, for the first time, distinct American Indian and Asian fertility rates are projected. Fourth, the National Center for Health Statistics (NCHS) recently began to

provide tabulations where each newborn is given its race dependent on the race of its mother.¹ This report is the first set of projections to reflect this new rule. The

¹Previously, if the parents were of different races, the following rules were used to assign race to the newborn child. When only one parent was White, the child was assigned the other parent's race. When neither parent was White, the child was assigned the father's race with one exception; if the mother was Hawaiian or part-Hawaiian, the child was assigned to Hawaiian.

(National Center for Health Statistics: Vital Statistics of the United States, 1988, Vol. I, Natality. DHHS Pub. No. (PHS) 90-1100. Public Health Service, Washington. U.S. Government Printing Office, 1990.)

Table B. 1990 Total Fertility Rates, by Race or Origin of Child and Race or Origin of Mother

Item	White	Black	American Indian ¹	Asian ²	Hispanic origin ³
Race of child (old rule) . .	1,926	2,631	3,544	2,569	2,687
Mother rule (new rule) . .	1,970	2,510	2,921	2,372	2,687
Percent difference (between new rule and old rule)	1.5	-4.3	-21.3	-8.3	0.0

Note: Fertility rates were calculated from preliminary data. These rates may not agree with other released data.

¹American Indian represents American Indian, Eskimo, and Aleut.

²Asian represents Asian and Pacific Islander.

³Persons of Hispanic origin may be of any race.

⁴Hispanic origin always reported by ethnicity of mother.

effect of this rule change is shown in table B. Hispanic origin has always been reported based on the ethnicity of the mother; hence, the rule change does not alter the tabulations of births by Hispanic origin.

The mortality component varies the least of the three components, and thus the assumptions have changed minimally from previous reports. This report does, however, use the term "life expectancy" instead of "mortality" to help avoid confusion in the highest and lowest series (i.e., "low life expectancy" means the opposite of "low mortality"). Unlike previous projections, this report does not assume convergence of mortality by race nor a fixed sex differential. Instead, the average annual rate of change from 1980 to 1990 was projected from 1990 to 2050 for each age, sex, race, and ethnicity group. For the first time, the impact of AIDS is included in the middle series. Finally, the American Indian and Asian populations have their own distinct mortality trends and patterns based on NCHS data, unlike earlier projections where both populations were assumed to have rates of mortality equal to White rates.

INTRODUCTION

This report includes population projections of the United States by age, sex, race, and Hispanic origin for the years 1992 to 2050. These numbers are based on an estimated July 1, 1991 resident population consistent with the 1990 census as enumerated, and are projected forward using the cohort-component method with alternative assumptions for future fertility, life expectancy, and net immigration levels.

For each of the components of change—fertility, life expectancy, and net immigration—three different assumptions about the future are applied. The series using the middle assumption for each component is designated the "middle series."

Projections of the middle series are shown annually by age, sex, race, and Hispanic origin to 2005, and quinquennially thereafter to 2050. Alternative series are

shown by five-year age groups and by race and Hispanic origin quinquennially from 1995 to 2050. Nine principal alternative series are shown in this publication.

Using the cohort-component method, the components of population change are projected separately for each birth cohort (persons born in a given year). The base population is advanced each year by using projected survival rates and net immigration by single year of age, sex, race, and Hispanic origin. Each year a new birth cohort is added to the population by applying the projected fertility rates by race and Hispanic origin to the January 1st female population.

This set of projections disaggregates the population into detailed race crossed by Hispanic origin categories. The four races are White; Black; American Indian, Eskimo, and Aleut; and Asian and Pacific Islander. Each race then is split into Hispanic origin and non-Hispanic origin, creating eight race/ethnic groups, four Hispanic race groups and four non-Hispanic race groups. The components of change are individually applied to each group to project the next year's population.

These results have been modified by use of the inflation-deflation variant of the cohort-component method.² This method does not correct for the net undercount in the 1990 census. This procedure holds constant the size and age-sex-race-Hispanic origin composition (estimated by Demographic Analysis) for those persons not enumerated by the 1990 census. The inflation-deflation variant yields a population distribution in each projected year which is similar to that which would result if a census with the 1990 pattern of undercount (as estimated by Demographic Analysis) were conducted in that year. It therefore preserves the actual pattern of population change by age group rather than by cohort. If the cohort-component method alone were used, the effects of under-enumeration would age as the population grew older, i.e., the unenumerated 1990 population would remain with the cohorts as they aged.

Similar to previous projections, the population in the Armed Forces overseas was held constant in size and age-sex-race-Hispanic origin composition throughout the projection period. In this case, however, the projected population is resident population only, excluding the population of Armed Forces overseas. Therefore, to accurately move the resident population forward in time, members in the Armed Forces overseas need to be subtracted as they leave the resident population going overseas and added when they returned. This procedure assumes no deaths or births to the Armed Forces overseas. Without this movement of the Armed Forces population in and out of the resident population, the

²For a detailed explanation of this procedure, see Current Population Reports, Series P-25, No. 1045, *United States Population Estimates, by Age, Sex, Race, and Hispanic Origin: 1980 to 1988*, by Frederick W. Hollmann.

starting cohorts of ages 18, 19, and 20 in 1991 would always appear relatively smaller than younger cohorts when they reach those ages.

Assumptions

In the middle series, age-specific fertility rates are held constant at slightly below 1990 levels for the non-Hispanic White; non-Hispanic Black; and the non-Hispanic American Indian, Eskimo, and Aleut. However, a 10 percent decrease in fertility rates after 2000 is assumed for the Hispanic origin and the non-Hispanic Asian and Pacific Islander populations because the share of their fertility contributed by the foreign born is expected to decrease. Unlike previous projections, convergence of the birth rates by race and origin is not assumed.

Table C. Principal Fertility, Life Expectancy, and Net Immigration Assumptions

	1992	2050 level		
		Low assumption	Middle assumption	High assumption
Fertility	2,052	1,833	2,119	2,522
Life expectancy	75.8	75.3	82.1	87.6
Yearly net immigration (thousands)	880	350	880	1,370

In the alternative series, the low fertility assumption shows a decrease in fertility rates by 10 percent for the non-Hispanic White population, and a decrease of 20 percent for the other three race groups and the Hispanic origin population. Conversely, the high fertility assumption shows an increase in fertility rates by 10 percent, again for all groups except the non-Hispanic White rates which increase by 20 percent. These alternative levels are reached by 2010.

Life expectancy is assumed to increase slowly in the middle series from 75.8 years in 1992 to 82.1 years in 2050. This series replicates the mortality improvement experienced in the decade of the 1980's for the next 60 years, but also includes some negating effects of AIDS. The impact of AIDS is assumed to slowly diminish after the turn of the century. No race/sex convergence is assumed.

Life expectancy in the alternative series could reach a high of 87.6 or drop to slightly below its current level to 75.3. The high life expectancy series replicates the pattern of rapid improvement which occurred from 1970 to 1980, with no major impact of AIDS. The low life expectancy series, conversely, holds current mortality rates constant, with an increase over the next 15 years in deaths due to AIDS. This uses a 1990 base life table

with AIDS projected to increase linearly up to the year 2005, then remain constant to 2050.

Net immigration is assumed to remain constant throughout the projection period at 880,000 per year (about 1,040,000 immigrants and 160,000 emigrants). This reflects the 1990 immigration law changes and current knowledge of emigration, undocumented migration, and movement to and from Puerto Rico. The high assumption of 1,370,000 includes higher numbers of these components (with a decrease in emigration), consistent with Immigration and Naturalization Service suggestions that the cap on legal immigration may be pierced by family-sponsored immigration, and that refugee immigration could potentially increase. The low assumption of 350,000 projects that immigration would decrease and emigration would increase, with legal and refugee immigration similar to the level in the mid 1980's (about 500,000), net undocumented immigration would decrease to 100,000, and emigration increase to 260,000. Both the high and the low levels are first reached in 1995.

PROJECTED POPULATION TRENDS

Population Size and Growth

Over the last 60 years the population of the United States grew by almost 130 million to 252 million in 1991. In the middle series, the population is projected to increase another 130 million over the next 60 years to 383 million, a 50 percent increase. The lowest and highest series project the population to be only 276 million or possibly as high as 507 million respectively by 2050 (table D).

The U.S. population is projected to reach 275 million in 2000, a growth of 25.4 million or 10.2 percent since 1990. During the 1980's the population grew 21.7 million

Estimates and Projections of Resident Population: 1950 to 2050

Source: Tables 1 and 4 and P-25, Nos. 1045 and 1089.

or 9.5 percent. Only during the 1950's were more people added to the nation's population than are projected to be added during the 1990's.

The average annual rate of population growth would decrease in the middle series by over 50 percent, from 1.04 per 1,000 population between 1990 and 1995 to 0.49 between 2040 and 2050, though a short plateau between 2005 and 2015 temporarily slows this steady decline (table E). Because the annual number of immigrants is assumed to remain constant, slowing natural increase is the primary force causing this decrease in the rate of change. The projected fall of the rate of natural increase is predominately due to a dramatic increase in the crude death rate. Even so, natural increase would not drop below zero during the projection period, and the population would not stop growing in the middle series. After 2020, the U.S. would grow more slowly than ever before.

The lowest series projects the population to grow slowly, peak in the year 2027 at 287 million, then gradually decline. The average annual percent change would decrease throughout the projected period. Conversely, the highest series projects the population to increase quite steadily over the next 60 years with most rapid growth between 1995 and 2020, over 1.2 average annual percent change. After 2020, this rate would begin to decline as the survivors of the baby boom reach the high mortality ages.

Table E. Average Annual Percent Change in Population: 1985 to 2050

Age Distribution

Median age. In all the projection series, the future U.S. population will be older than it is now. In the middle series, the median age of the population will steadily increase from 32.8 in 1991 to 35.7 in 2000, peak at 39.4 in 2035, then decrease slightly to 39.3 by 2050 (table F.).

Source: Tables 2 and 3 and Current Population Reports, Series P25, *U.S. Population Estimates, by Age, Sex, Race, and Hispanic Origin: 1980 to 1991*, forthcoming.

Baby Boom. This increasing median age is driven by the aging of a major part of the population born during the Baby Boom after World War II (1946 to 1964). About 30 percent of the population in 1992 were born during the Baby Boom. As this population ages, the median age will rise. People born during the Baby Boom will be between the ages of 36 and 54 at the turn of the century. In 2011, the first members of the baby boom will reach age 65 and the Baby-Boom population will have decreased to 25 percent of the total population (in the middle series). The last of the Baby Boom population will reach age 65 in the year 2029. By that time, the Baby-Boom population is projected to be only about 17 percent of the total population.

Dependency ratio. The dependency ratio indicates how many children and elderly there would be for every 100 people of working age, between 18 and 64 years. The middle series projections indicate that the dependency ratio would decrease from 62.9 in 1992 to 60.0 in 2010. As people born during the Baby Boom begin to reach age 65, this ratio is projected to increase to 67.4 by 2020, 77.5 in 2030, and 78.0 in 2040.

Younger ages. The age group under 18 will increase by about 5 million by the turn of the century, then grow another 18 million by 2050. However, during the projected period this age group's proportion of the total population may never be as large as it is today, declining from almost 26 percent of the total population in 1992 to 23 percent in 2050.

The elementary school-age population (5 to 13) would increase by over 4 million during the 1990's to over 36 million by 2000. After 2002, smaller cohorts born near the end of the twentieth century would cause this population to decline for 8 years. However, this

population would start to increase again by 2011. By 2020, the elementary school population would increase to over 38 million and to over 44 million by 2050.

The high school-age population (14 to 17) is projected to continue to grow from almost 14 million in 1992 to over 17 million in 2005. As the smaller cohort born near the end of the twentieth century enters high school, the high school population would start to decline by 2010. After 2015, the high school-age population would begin to increase again to almost 17 million by 2020 and almost 20 million by 2050.

The age group of 18 to 21—the primary group entering the labor force, college, and the military—is projected to soon begin to grow again for the first time since peaking at 17.4 million in 1980. This age group is projected to decline from 15.2 million in 1991 to 13.8 million in 1994, then increase to 15.7 million in 2000 and 17.8 million in 2010 (a new all-time high).

The population aged 25 to 44 would scarcely change size from 1991 to 2000, but the number of 35 to 44 year olds would grow 5.4 million while those aged 25 to 34 would decrease 5.5 million.

None of the total population growth of 23 million from 1991 to 2000 is projected to occur in the population under age 35.

The age group of 45 to 54 year olds is projected to increase the most (44 percent) from 1991 to 2000. It would grow from 25.7 million in 1991 to 37.1 million in 2000. This growth of 11.4 million represents one-half of the nation's expected total growth during this period.

The elderly. The oldest age groups are projected to increase during the next 60 years, both in number and as a proportion of the population. In 1992, there are expected to be 32 million people aged 65 and over, about 12.6 percent of the population. By 2000, this group would grow to almost 35 million and 12.7 percent of the population, and by 2050, almost 79 million and represent 20.6 percent of the population.

However, during the next two decades the elderly population (aged 65 and older) is projected to grow more slowly than it has in many decades. From 1991 to 2010, it would grow only 1.2 percent a year, compared with its average annual growth of 2.4 percent from 1950 to 1990.

After 2010, when the survivors of the Baby Boom start to enter this age group, the proportion 65 and over would increase dramatically from 13.3 percent in 2010 to over 20 percent by 2030, from 39.7 million elderly persons to 69.8 million. The average annual rate of increase for this age group during those 20 years would be 2.8 percent.

The population aged 85 and over would be the fastest-growing broad age group, doubling in size from 1991 to the year 2020, and increasing fivefold by the year 2050. In 1992, 3.3 million people would be age 85 and over. By 2050, this figure would increase to over 17

million. Both increased life expectancy and the increased number of people entering these age groups contribute to the population explosion in these older ages.

The population 100 years and over, though numerically small, is also projected to grow substantially. In 1992, the population would be 45,000, growing to 77,000 by 2000, and to over 1 million by 2050.

In the future, the ratio of males to females in the elderly population may become more balanced. This results from the assumption that male life expectancy will continue to improve faster than that of females.

Currently, women dominate the 65-and-over population with a 60-percent majority. By 2050, the female proportion of this age group is projected to decrease to slightly more than half (54 percent). Moreover, this changing sex ratio is also evident in the oldest age groups. The 85-and-over population would change from about 72-percent female in 1992 to 63-percent female in 2050. In the age group 100 and over, the change would also be noticeable, dropping from 80-percent female in 1992 to 75 percent in 2050.

Race and Hispanic Origin Distribution

Table 1 shows the future changes in race/ethnic composition of the population according to the middle series. The race and Hispanic origin distribution of the U.S. population is projected to become more diverse. As the Black, American Indian, Asian, and Hispanic populations increase their proportions of the total population, the White population proportion would decrease. This decrease is even more pronounced for non-Hispanic White.

By the turn of the century, the White proportion of the population is projected to decrease to less than 82 percent of the population. About 13 percent of the population would be Black, 4.5 percent of the population would be Asian and Pacific Islander, and the remaining 0.9 percent of the population would consist of American Indians, Eskimos, and Aleuts. People of Hispanic origin would constitute 11 percent of the total population. The White population who are not of Hispanic origin would be less than 72 percent of the total population.

By 2050, 71.8 percent of the population is projected to be White, 16.2 percent will be Black, 1.2 percent would be American Indian, Eskimo and Aleut, and 10.7 percent will be Asian and Pacific Islander. The Hispanic-origin population would increase to 21.1 percent, and the non-Hispanic White population would decline to 52.7 percent.

Similar distribution changes are projected to occur in both the highest and lowest series, though less so in the lowest series and more so in the highest series. However, compared to the middle series, the Black population would not have as large a share in either alternative series. In the lowest series, both the White population and the American Indian population would have a larger share of the total population than in the middle series, while all the other groups would have a smaller share. In the highest series, the Asian and Hispanic populations would have larger shares of the total population than in the middle series.

Trends and population growth. The White population is projected to be the slowest-growing race group during the next 60 years, increasing in the middle series only 29 percent by 2050. In fact, the non-Hispanic segment of the White population would stop growing by 2029, largely by virtue of the cessation of net increase, at a peak of 207.7 million and then slowly decrease. Yet by 2050, the total White population would contain about 62 million more people than in 1992. The increase by the total White population after 2029 would be due entirely to growth in the number of White Hispanics.

Non-Hispanic Whites are likely to contribute less and less to the total population growth in this country. Although non-Hispanic Whites make up almost 75 percent of the total population in 1992, they would contribute only 30 percent of the total population growth

Table 1. Percent Distribution of the Population, by Race and Hispanic Origin

(As of July 1. Resident population. Consistent with the 1990 Census, as enumerated)

¹Persons of Hispanic origin may be of any race.

Source: Table I.

between 1992 and 2000. This percentage of growth would decrease to 21 percent between 2000 and 2010, and decrease to 13 percent from 2010 to 2030. The non-Hispanic White population would contribute nothing to population growth after 2030 because it would be declining in size.

With almost twice the White population's annual rate of change in 1992, the Black population would grow at a faster pace than the White population. The Black population would increase over 4 million by 2000, almost 9 million by 2010, and over 19 million by 2030. During the next 60 years, the Black population would grow by almost 100 percent to 62 million. Therefore, the Black share of the total U.S. population is expected to slowly increase from 12 percent in 1992 to 13 percent in 2000, 14 percent in 2010, 15 percent in 2030, and 16 percent in 2050.

The Asian and Pacific Islander population is projected to continue to be the fastest-growing race group with annual growth rates that may exceed 4 percent during the 1990's. By the turn of the century, the Asian population would expand to over 12 million, double its current size by 2009, triple by 2024, and quadruple by

2038. By the middle of the next century, this population group would have expanded to 5 times its current size, to 41 million.

In the middle series, the Asian population's share of the U.S. population is projected to increase from 3.3 percent in 1992 to 4.5 percent in 2000, 6 percent in 2010, 8 percent in 2030, and 11 percent in 2050. This population would account for 19.2 percent of the nation's growth from 1992 to 2000, 22 percent from 2000 to 2010, 25 percent from 2010 to 2030, and 32 percent from 2030 to 2050. Each year after 2002, the Asian and Pacific Islander population would add more people to the population of the United States than would the non-Hispanic White group.

Immigration is an integral part of this group's growth. Throughout the projection period Asian immigration would be higher than natural increase. In fact, the number of Asian immigrants is projected to exceed the number of Asian births for the next thirty years. In total, over 3 million surviving net Asian immigrants and their surviving descendants would be added to the U.S. population between 1991 and 2000, and 30 million post-1991 surviving Asian net immigrants and their surviving descendants would be added to the population by 2050.

Figure 7.

**Average Annual Percent Change in Population,
by Race and Hispanic Origin: 1992 to 2050**

Note: Based on the middle series.

¹Persons of Hispanic origin may be of any race.

Source: Computed from table 1.

In contrast to the growth trends of the Asian population, the American Indian, Eskimo, and Aleut population would experience nearly all of its growth by natural increase. The American Indian population is projected to grow steadily, from 2.2 million in 1992 to 2.4 million in 2000, 2.8 million in 2010, 3.6 million in 2030, and 4.6 million in 2050. The percent of the population that is American Indian, Eskimo, and Aleut would rise from 0.8 percent in 1992 to 1.0 percent around 2020 and 1.2 percent in 2050.

Growth of the Hispanic-origin population will probably be a major element of the total population growth. The Hispanic population would contribute 33 percent of the nation's population growth from 1992 to 2000, 37 percent from 2000 to 2010, 43 percent from 2010 to 2030, and 57 percent from 2030 to 2050. This growth of the Hispanic population over the next 60 years may be influenced more from natural increase than immigration.

By 2000, the Hispanic-origin population may increase to 31 million. By 2020, the Hispanic population is projected to double its current size to almost 49 million, and more than triple its current size to over 80 million by 2050. In fact, after 1995, the Hispanic population is

projected to add more people to the United States every year than would the non-Hispanic White population (or any other group).

Age Structure. Hispanics were the youngest population group in 1990 with half the population younger than age 26. As the total U.S. population ages, the Hispanic population is projected to age quicker than both the American Indian and Black populations. The median age of the Hispanic population would be higher than the American Indian population's median age by 2010, and higher than the Black population's median age by 2045.

The White population is projected always to be the oldest segment of the population. In 1992, the non-Hispanic White median age would be 36, increasing to a peak of age 45 by 2040.

As specific age groups increase or decrease more rapidly than the entire population, they signal possible on-coming trends. For instance, due to lower birth and immigration rates, the non-Hispanic White population under age 20 would be less than 50 percent of the total population under age 20 by the year 2035.

COMPONENTS OF CHANGE

Births

In the middle series the total number of births is expected to decrease to below 4 million during the 1990's as the tail end of the baby boomers are finishing childbearing. By 2003, the crude birth rate may drop to a record low of 13.8 births per thousand population.

After the turn of the century, the crude birth rate is projected to rise, and the number of births would reach over 4 million again by 2007, instigated by an increasing number of women in their childbearing years. Many of these births will be the grandchildren of the baby boomers. The number of births may continue to increase throughout the end of the projected period. In fact, by 2014 the annual number of births would exceed the highest annual number of births ever achieved in the United States. At the same time, the crude birth rate would slowly decrease again from 14.0 to a low of 13.2 by 2029. The annual number of births would continue to rise, setting new records each year. By 2027, births may exceed 4.5 million and top 5 million by 2047.

These opposing trends of increasing births and decreasing crude birth rates reflect two characteristics of the population. First, a large proportion of the population may not be in their childbearing years or may not be

having children. In this case, a major proportion of the population (the baby boom generation and its echo generation) would be too old to bear children. The increase in births, however, indicates the second characteristic of the population: a slowly increasing total fertility rate combined with an increasing number of women in their childbearing years.

In the mid-2030's the effects of the baby boom appear again. This slight rise in the crude birth rate reflects the births of the great-grandchildren of the original mid-20th century baby boom. However, the effects of the baby boom on fertility would decline for each new generation. At the same time immigration and the changing race/ethnic fertility patterns would eventually obscure the echo effects of the baby boom.

In the middle series, the total fertility rate is projected to increase, consistent with the increasing proportion of Hispanic births. In 1992, the total fertility rate would be 2,052 per 1,000 women, increasing moderately to 2,119 by 2050. In the lowest series, the total fertility rate is projected to decrease to 1,833 and in the highest series it would increase to 2,522 by 2050.

Birth trends by race and Hispanic origin. Birth trends are projected to differ substantially by race and Hispanic origin. Some of this difference will be caused by the age structure of the differing groups, easily observed by the

Figure 8.
Annual Levels of Net Growth, Births, Deaths, and
Net Immigration: 1992 to 2050
(In millions)

Note: Based on the middle series.

crude birth rate. Other differences will be attributed to the groups' various levels of fertility.

Currently, about 66 percent of all births are non-Hispanic White. That percentage is expected to fall to 61 in 2000, 56 in 2010, 48 in 2030, and 42 in 2050. All other race and ethnic groups would increase their share of births. The percentage of all births that are Black is projected to rise from 17 percent in 1992 to 22 percent in 2050. The percentages in those years for Asians are 4 and 11, for American Indians are 1 and 2, and for Hispanics are 14 and 26.

In the middle series, the total crude birth rate is projected to gradually decrease, though the pattern varies significantly by race and Hispanic origin. For example, although the Hispanic origin population would have the highest crude birth rate in 1992 at 23.1, this rate declines very sharply to two-thirds of its original rate by 2050. In fact, by 2025, this group's rate drops below the Black and the American Indian populations' crude birth rates. Conversely, the American Indian population's crude birth rate decreases minimally, fluctuating between a high of 19.1 to a low of 18.2 during the sixty year period. Though the Black and American Indian populations have very close fertility rates, by 2026 the continuous decline in the Black fertility rate would bring it below that of American Indians. Moreover, the level of the non-Hispanic White crude birth rate is projected to drop swiftly from 13.9 in 1992 to 11.9 in 2000. Thereafter, the non-Hispanic White's crude birth rate then would decrease less than the decrease in Black, Asian, or Hispanic crude birth rates.

Table J shows the influence of Hispanic fertility across all the races. The Hispanic total fertility rate is higher than all the other groups in 1995 except for the American Indian, and is assumed to slowly decline after 2000 in the middle series. Although the fertility levels of the non-Hispanic groups are assumed to remain the same throughout the projected time period (barring the assumed decline in the Asian and Pacific Islander rates), the fertility rates of the four race groups including

Hispanics (left side of table J) all shift as the proportion of Hispanic births changes for each race. For instance, because the non-Hispanic White fertility rates are projected to be lower than the Hispanic rates, a noticeable increase occurs by 2050 from 1,956 to 2,009 births per 1,000 White women. At the same time, however, the non-Hispanic White birth rate remains constant at 1,850. Yet, for the Black and the American Indian populations, the projected decrease in Hispanic fertility would cause the Hispanic rate to fall below the constant rates of Blacks and American Indians, and would effectively decrease those rates by the middle of the next century. In contrast, the assumption of declining fertility rates for the non-Hispanic Asians and Pacific Islanders contributes more to the decrease in the API rates than the small influence of Hispanic births.

The proportional share of the total number of births also would change dramatically. As the non-Hispanic White population decreases its share of total births, the other groups would gain. Indeed, the non-Hispanic White population is projected in the middle series to lose its majority share of births by 2025. Both the Hispanic and American Indian proportions of births would almost double by 2050, and the Asian proportion of births would triple.

Deaths

Between 1992 and 2050 the total number of annual deaths is projected to increase by 85 percent, from 2.2 million in 1992 to 4.1 million in 2050. Although life expectancy at birth would increase from ages 72.2 for males to 78.8 and 79.0 for females to 85.4, the increased volume of deaths is instigated by the increased number of people in older ages where mortality is high.

The crude death rate would steadily increase until the latter half of the 2040's when the rate would peak at 10.8. The crude death rate in the United States has not been this high since before 1930.

Figure 9.

Components of Population Change in the Middle Series: 1992 to 2050

(Rate per 1,000 population)

Most of the deaths would occur to the non-Hispanic White population. Although their share is projected to decrease from 83 percent to 66 percent by 2050, the non-Hispanic White population is more at risk of dying because of their concentration in the older ages. For similar reasons, the percentage of deaths occurring to the Hispanic-origin population is projected to triple by 2050 as this group also ages.

Immigration

According to the middle series, the U.S. population in the year 2000 is projected to be 8.8 million (3.3 percent) larger than it would have been if there had been no net immigration after July 1, 1991. This figure would increase to 21 million by 2010, and 49 million by 2030. By the middle of the next century, the U.S. population may include 82 million post-1991 immigrants and their descendants, or 21 percent of the population.

As natural increase declines, the compounding impact of immigration on the U.S. population growth would increase each year. In 1992, about 33 percent of the growth in the population would be caused by net immigration. By the turn of the century, net immigration would account for over 60 percent of the post-1991 population increase. Eventually, about 93 percent of the population growth during the year 2050 may be due to post-1991 net immigration.

In all projection series, the Hispanic population is assumed to have the highest number of annual immigrants. The middle series projects 880,000 net immigrants a year composed of 324,000 Hispanics; 323,000

non-Hispanic Asians; 174,000 non-Hispanic Whites; and 60,000 non-Hispanic Blacks.

If, however, there were no net immigration after 1991, the racial composition of the U.S. population would be quite different than projected. For instance, by 2050 the Black population would grow to 17 percent of the total population, and the American Indian and the Asian populations combined would make up about 5 percent of the total population. The Hispanic population would be less than 16 percent of the total population, with 30 million people less than projected with immigration. The non-Hispanic White population would still be over 62 percent of the U.S. population in 2050, in spite of this group's decline in population growth after 2023.

PROJECTION SERIES WITH ALTERNATIVE COMPONENT ASSUMPTIONS

Most of the preceding results are based on the middle series, assuming the middle levels of fertility, life expectancy, and net immigration. The actual future course of population growth, however, could vary considerably from the middle series because of variations in fertility, life expectancy, and net immigration. Though some examples of the extreme lowest and highest projected assumptions are presented, other alternative series created by varying only one component illustrate other possible outcomes. Table K illustrates the future population based on these various component assumptions. Obviously, the further into the future, the more the

Table K. Population with Different Component Levels: 1995 to 2050

Source: Tables 2 and 3.

alternative assumptions will deviate from the middle series. In the near future, immigration affects the growth of the population more than births or deaths. That is because the alternative net immigration levels are reached sooner than are those for life expectancy or fertility. However, since immigration is assumed to remain constant throughout the projected period while at the same time the population continues to increase, the immigration component of population growth would decrease proportionally in importance.

Making a Choice Among 10 Series

Although the middle series is presented in great detail, there are nine other alternative projections series. For most purposes, the middle series should suffice. However, those interested in a specific population group may need to pay more attention to alternative series, detailed in tables 3 and 4. Two major alternative series,

Highest and Lowest, show the extreme limits of the future total population based on these component assumptions. The seven other principal alternatives show the effects of independently varying each of the component assumptions (fertility, life expectancy, and net immigration), while leaving the other components at the middle level. These are detailed with their descriptive names in table L. Using these series, the effects on future population size or the age-sex-race-Hispanic origin composition of a change in just fertility, just life expectancy, or just net immigration can be determined. Although previous Census Bureau projections provided 30 alternative series, only the principal 10 series were generated for this set of projections.

DETAILED METHODOLOGY

The Cohort-Component Framework

Six sets of data are required to generate these population projections using the cohort-component model.

Table L. Principal Fertility, Mortality, and Net Immigration Assumptions in Each Projection Series

Principal series name	Fertility	Life expectancy	Net immigration	Old series number ¹
Middle.....	Middle	Middle	Middle	14
Lowest.....	Low	Low	Low	19

Low life expectancy.....	Middle	Low	Middle	23
High life expectancy.....	Middle	High	Middle	5
Low net immigration.....	Middle	Middle	Low	11
High net immigration.....	Middle	Middle	High	17
Zero net immigration.....	Middle	Middle	Zero	29

¹The previous set of projections produced by the Census Bureau had 30 alternative series. See Current Population Reports, P-25, No. 1018. Only 10 alternatives were generated for this set of projections.

These are a base year population, projected fertility rates, projected survival rates, future net immigration statistics, 1990 inflation-deflation rates, and an estimated Armed Forces overseas population. The most difficult aspect of producing these population projections involves deriving the base-year starting points and rates. Each data set is organized into 16 different race/ethnic/sex matrices with a cell for each year of age 0 to 100 and over. The sixteen matrices are White; Black; American Indian, Eskimo, and Aleut; Asian and Pacific Islander—by Hispanic origin (Hispanic and Not Hispanic) and by sex. The sum of all the cells in all 16 matrices equals the total population.

Starting with a July 1, 1991 modified population estimate based on the 1990 census, each cell is inflated by Demographic Analysis to correct for persons not included in the population count in 1990. Then each age/race/ethnic/sex cell is survived forward to July 1, 1992 by applying the appropriate survival rate.

The population under 1 is created by first calculating the population of women exposed to the risk of childbearing. Generally this involves averaging the July 1, 1991 and July 1, 1992 inflated female population, of each race/ethnic group by single years of age between the ages 14 through 49.³ Then, the corresponding age/race/ethnic specific fertility rate is applied to this averaged female population to produce, after aggregation, the total number of births by race/ethnicity for that fiscal year. The assumed sex ratio for each group is used to divide the births into males and females. Finally, the number of births by sex and race are survived forward to July 1, 1992.

After the births are calculated, net immigration by age/sex/race/ethnicity are added. Then the movement of the population of Armed Forces overseas are applied to the population by detailed group. Next, the population is deflated to be consistent with the 1990 census count. A small pro rata adjustment is made to the deflated age estimates in each sex/race/ethnic group to bring them in exact agreement with an independent estimate of the total population of each group.

Finally, the 16 groups are summed, creating the groups most frequently requested, and are displayed in this report. This includes adding the Hispanic and Not Hispanic groups for each race to make a total population by age/sex for each race, and adding the 8 Hispanic-origin matrices to get the total age/sex Hispanic-origin population. As these groups are added, new total rates are derived for these new groups. The same set of procedures when applied to the July 1, 1992 population would generate the July 1, 1993 population. This process is continued until 2050.

³These estimates were modified using the $0.125 \times (\text{population aged } X-1) + 0.75 \times (\text{population aged } X) + 0.125 \times (\text{population aged } X+1)$ formulation to approximate the female population aged X in each year which was able to experience a birth at age X .

The Base Population

The beginning population of these projections is the July 1, 1991 estimate.⁴ Because this estimate reflects births by race of child, a slight reorganization of the zero and one-year-old populations by race was made to account for the new mother rule of race designation of births used in these projections. These estimates are consistent with the 1990 census count, but cannot be directly compared to the published results by age and race because modifications were made to the data to correctly place each person in an appropriate age and race category.⁵ This was done to adjust for age misreporting and the reporting of an unspecified race in the 1990 census.

Fertility

Assumptions. As in the past, three different future fertility levels are used. These are derived from analysis of natality statistics for five groups of women by race group and Hispanic origin. Assuming that the pattern of fertility would be the same for all Hispanic women, across all races, we derived levels for Hispanic-origin women and the remaining four non-Hispanic race groups: non-Hispanic White; non-Hispanic Black; non-Hispanic American Indian; and non-Hispanic Asian. The levels for each total race group would then be the combination of the Hispanic and non-Hispanic proportions of that race group. As these proportions change, so would the combined fertility levels.

In 1989, NCHS changed their method of reporting race of births to reflect the race of the mother. The projected fertility levels and rates in this report use this new rule.

Several fertility assumptions in this report are founded on past trends. First, this projection will not assume race/ethnic fertility convergence. Historical data shows that the major differences between White and Black fertility is timing, that is, Blacks tend to have their children at earlier ages than Whites. After age 25, however, White and Black fertility has been about the same. Yet, there is no compelling evidence of overall convergence of Black-White or any race-ethnic fertility. Second, in the last decade, many women delayed the start of childbearing until their late 20's or 30's. This recent shift to a new age pattern of childbearing is assumed to remain constant. Third, since the end of the Baby Boom, completed cohort fertility has remained

⁴U.S. Bureau of the Census, Current Population Reports, Series P25, *U.S. Population Estimates, by Age, Sex, Race, and Hispanic Origin: 1980 to 1991*, by Frederick W. Hollman, forthcoming.

⁵U.S. Bureau of the Census, *Age, Sex, Race, and Hispanic Origin Information from the 1990 Census: A Comparison of Census Results with Results where Age and Race have been Modified*. 1990 CPH-L-74, August 1991.

about the same. Therefore, there appears to be no reason to assume a change from the fertility levels for Whites, Blacks, and American Indians.

The fertility levels in the middle series are based on the premise that foreign-born women may have higher fertility than native-born women. Thus, Hispanic and Asian fertility are assumed to decrease after 2000 as the share of their fertility contributed by the foreign-born will decrease. The non-Hispanic White, non-Hispanic Black, and non-Hispanic American Indian fertility would remain constant throughout the projected period.

In the low series, the fertility rates is assumed to fall for all races and Hispanic origin, decreasing 10 percent for non-Hispanic White and 20 percent for the other four groups by the year 2010. The reverse is assumed for the high series. The high series would have an increase in rates, up 20 percent for non-Hispanic Whites, and 10 percent for the other four groups by 2010.

Creation of 1990 central birth rates. The birth rates for these projections are based on 1990 fertility rates. The beginning rates were created using NCHS natality data and 1990 census population figures.⁶ Because only provisional data were available for 1990, 1989 final detailed data were controlled by the provisional 1990 number of births (corrected for underregistration). Births for each race group—White, Black, American Indian, and Asian—were divided by a 1989 (1990 census based) population. Because the base population for these projections was a 1990 census base, the base rates needed to be consistent with this new population count and distribution. Using a time series model,⁷ the White 1990 birth rates were forecast, adjusted to the provisional 1990 birth totals. Using a ratio to the White 1989 rate, the birth rates were derived for the other races: Black, American Indian, and Asian.

Birth rates for the Hispanic-origin population are also based on NCHS birth data. In 1989, these data included 47 states and the District of Columbia, covering about 99.2 percent of the total U.S. Hispanic population (based on 1990 census figures). The Hispanic rates were held constant at 1989 levels. Non-Hispanic rates were created by extracting the Hispanic data out of each race for both population and births. Finally, each group's total fertility rate was rounded down slightly.

Life Expectancy

Assumptions. As in the last Census projections, three basic mortality assumptions are used. The middle life expectancy assumptions reflects a slow improvement in

life expectancy. The last 10-year trend of mortality improvement, from 1980 to 1990, is replicated, and some additional impact of AIDS is included.⁸ The incidence of AIDS is projected to increase linearly until the turn of the century. After 2000, mortality from AIDS will slowly decrease, returning to the 1990 level of AIDS mortality by 2050. The low life-expectancy series assumes that current mortality rates will continue, with an increase over the next 15 years in deaths due to AIDS. This uses a 1990 base lifetable with AIDS projected to increase linearly up to the year 2005, then remain constant. The high life-expectancy assumption, or rapid improvement series, replicates the pattern of mortality between 1970 to 1980, thus ignoring the impact of AIDS.

Lifetables. The 1990 lifetable was based on NCHS death data (final 1989 and sample 1990) for age, sex, race, and Hispanic origin. Race detail provided deaths only for the White, Black, and "Other" populations. To obtain detailed deaths for the American Indian and the Asian populations, the "Other" group's deaths were split by subtracting death data provided by the Indian Health Service. The remaining deaths were considered to be Asian. Although this technique provided relatively adequate estimates of deaths for the American Indian and Asian races, the quality of mortality estimates for these two groups still remains questionable. The deaths for each race then were divided by their appropriate population estimate for July 1, 1990, creating death rates by five-year age groups, sex, race, and Hispanic origin.⁹ For the oldest age groups, where frequently age specific death data is often misreported, the rates were corrected using data from the Social Security Administration.¹⁰ The total death rates were then adjusted to agree with the estimated 2,162,000 deaths in 1990.

Non-Hispanic death rates by race were computed by extracting the Hispanic deaths from the total deaths for each race. By applying the proportional race distribution of the Hispanic-origin population to the total number of Hispanic deaths, the Hispanic deaths by race were derived. Thus, the remainder of deaths in each race were non-Hispanic.

The death rates used for every projected lifetable was based on the assumed change from the death rates used in the 1990 lifetable. In each assumption, sex and race differentials were not assumed to converge, but instead were determined by the rate of change applied to each individual group. The rates of change were computed based on adjusted-level death rates for 1970, 1980, and 1990. In the middle series, lifetables were

⁶All population denominators for fertility and mortality rates were based on 1990 census data adjusted for undercount using Demographic Analysis. These data were also modified for age and race.

⁷For more detail see U.S. Bureau of the Census, Current population Reports, Series P-25, No. 1018, *Projections of the Population of the United States, by Age, Sex, and Race: 1988 to 2080*, by Gregory Spencer, U.S. Government Printing Office, Washington, D.C., 1989.

⁸Paul R. Campbell, *Projected AIDS-Age-Sex-Race/Ethnicity Specific Death rates for the Period 1990 to 2005*, U.S. Bureau of the Census, Population Division, unpublished research (1991).

⁹See footnote 6.

¹⁰Burt Kestenbaum, *Administrative Records Perspectives on Mortality Among the Aged*, Social Security Administration, unpublished paper, 1991.

computed for 2000 (a turning point of the series) and 2050 (the end point). For the alternative series, a 2005 lifetable was created for the low life-expectancy assumption, holding the rest of the projected period constant at 2005 levels (i.e., AIDS gets no worse or better) and for the high life expectancy series, a 2050 lifetable was made. Survival rates were interpolated for each year between these points.

Net Immigration

The net immigration component used in these projections is composed of five types of migration, four which increase the population (immigration) and one that decreases the population (emigration). In the low, middle, and high net immigration, the same age/sex/race/ethnic ratio is used throughout, based on a 1991 estimate¹¹ of each migration type, but raked to the alternative levels for each type.

The levels of legal and refugee immigration are heavily influenced by Federal legislation and the political environment. Therefore, the middle assumption for this type of immigration is based on current levels and interpretation of current laws. The low alternative represents the legal and refugee immigration experience during the 1980's, whereas the high assumption reflects the possibility of piercing the legal cap on this type of immigration through modifications to the current law.

Undocumented immigration is difficult to measure. Currently, the Census Bureau's best estimate adds about 200,000 net undocumented immigration to the United States each year. Yet, the wide range between the low and high alternatives reflects some of the uncertainty of the actual number.

Puerto Rican and civilian citizen immigration levels exhibit the 1991 estimate of these components in the middle series, equally bounded by the low and high alternatives.

¹¹Unpublished data supplied by Frederick W. Hollmann, U.S. Bureau of the Census.

Table M. Components of Annual Net Immigration

(In thousands)

Net immigration component	Low net immigration assumption	Middle net immigration assumption	High net immigration assumption
Total net immigration	350	880	1,370
Legal/refugee	500	800	1,100
Undocumented	100	200	300
Puerto Rico	-	20	40
Civilian Citizens	10	20	30
Emigration	260	160	100

Source: Unpublished data.

Emigration, similar to the undocumented migration, contains some unknown qualities. Similar to previous Census Bureau projections, emigration is considered a constant, instead of a proportion of the total of all in-migration. However, unlike other projections, the low series does not show a lower number for emigration; in fact, it reflects a greater population exiting. Logically, if conditions exist for low in-migration (for example, an economic downturn), the same conditions or reasons would also drive more people out of the country. The reverse is assumed for the high series.

SELECTION OF ASSUMPTIONS, SENSITIVITY ANALYSIS, AND FORECAST ERROR

Uncertainty of Population Projections and Selection of a Range of Assumptions

The history of population has shown that unforeseen events can rapidly modify the demographic environment. The actual future population is never identical to the projected population. Although attention has been paid to problems of estimating the forecast accuracy of past population projections and the confidence intervals of future populations, many problems remain before a method can be developed for placing reliable confidence intervals around population projections. There is considerable controversy over the means of handling improvements in methods, changing variability in population growth rates, and other complicating factors. Given these difficulties, the highest and lowest series in this report were not chosen on the basis of a formal analysis of error ranges, but rather on the basis of the long-standing approach of projecting a "reasonable high" and a "reasonable low."

Past Forecast Error of Population Growth Compared to the Present Range of Assumptions

As an aid to those who would like to attempt a more formal approach to developing a confidence interval around the middle series, table N contains information

Table N. Root-Mean Square Error of Past Projections of the Growth Rate, Compared With Differences Between Selected Series of Past Projections

Number of years into projections period	Root-mean square error of past projections	Difference between the highest and middle series	Difference between the middle and lowest series
1	0.16	0.12	0.13
2	0.16	0.19	0.20
3	0.17	0.25	0.26
4	0.19	0.28	0.30
5	0.19	0.30	0.31
6	0.23	0.31	0.33
7	0.22	0.33	0.35
8	0.24	0.34	0.36
9	0.26	0.36	0.38
10	0.30	0.37	0.39
15	0.40	0.42	0.46
20	0.46	0.46	0.52

Note: Past projection data from the middle series of reports 601, 704, 952, and 1018. For earlier projections, a "middle" series was constructed by averaging the middle two series of four.

90 to 94 years	4.6	-6.8	14.8	-17.2	34.0	-36.7	46.6	-49.8
95 to 99 years	5.9	-9.2	19.5	-24.9	49.4	-48.9	69.1	-63.4
100 years and over	6.5	-14.3	22.5	-35.6	71.5	-65.1	112.9	-78.6
Total difference	2.4	-2.4	6.6	-6.7	17.4	-16.9	32.4	-28.0

Source: Derived from table 2, table 3, and unpublished data.

on the root-mean-square error in the past projection rates of population growth versus the actual rates. The table is based on available data from all U.S. Bureau of the Census population projections prepared in the last 30 years.

The root-mean-square error of projected growth rates in previous U.S. projections increased during the first few years of the projection period from 0.16 of a percentage point for one year into the projected period up to 0.46 of a percentage point after 20 years.

Table N also presents a comparison between the highest, middle, and lowest series with the calculated, root-mean-square errors for various time spans based on Census Bureau projections made during the last 30 years. If these root-mean-square errors of previous projections could be taken as estimates of the standard error around the present projections, then there would be roughly a two-thirds chance that a projected growth rate and actual growth rate will be within the range of the root-mean-square error shown. As the table N shows, the present projections do encompass this historical error range for the first 20 years. Again, it should be pointed out that these figures are merely illustrative and considerable work must still be done before a reliable method of establishing confidence intervals is available.

The data presented in table O demonstrate the sensitivity of the size of projected age groups to the differences in assumptions between the highest and lowest series. Results are shown for 2000, 2010, 2030, and 2050. By 2000, differences of greater than 5 percent exist only for the population under age 5 and over age 90, while ages between 30 and 80 have differences of less than 3 percent. In 2010, the highest or lowest series differ from the middle series by more than 5 percent at ages under 45 and over 70. By 2030, all age groups show a difference between the extreme and middle projection of over 5 percent, and ages below 25 and over 80 have difference of more than 20 percent. By 2050, only ages between 50 and 70 have differences between the extreme and middle series of less than 20 percent.

These differences result from the combined effects of alternative assumptions for fertility, life expectancy, and net immigration. Of course, differential fertility assumptions only affect the size of population age groups born after the beginning of the projection—under 4 by 1995, under 9 by 2000, etc. Differential life expectancy assumptions have slight effects on the younger population groups, moderate effects on the middle-aged, and substantial effects on the elderly population. Variation in net immigration would have its principal effects first in the

young-adult age groups and then in older ages as the earlier immigrants age. Such variations also would affect the future number of births.

RACE AND ETHNIC DEFINITIONS AND CONCEPTS

The racial classification used by the Census Bureau generally adheres to the guidelines in Federal Statistical Directive No. 15, issued by the Office of Management and Budget, which provides standards on race and Hispanic-origin categories for statistical reporting to be used by all Federal agencies. The race and Hispanic-origin categories are defined as the following:

American Indian, Eskimo, and Aleut. A person having origins in any of the original peoples of North America, who maintains cultural identification through tribal affiliation or community recognition.

Asian and Pacific Islander. A person having origins in any of the original peoples of the Far East, Southeast Asian, the Indian subcontinent, or the Pacific Islands. This area includes, for example, China, India, Japan, Korea, the Philippine Islands, and Samoa.

Black. A person having origins in any of the black racial groups of Africa.

Hispanic. A person of Mexican, Puerto Rican, Cuban, Central or South American or other Spanish culture or origin, regardless of race.

White. A person having origins in any of the original peoples of Europe, North Africa, or the Middle East.

AVAILABILITY OF MORE DETAILED DATA AND RELATED REPORTS

For each of the 10 series, the basic product of our methodology is a set of unrounded population counts by single years of age, sex, race, and Hispanic origin, for each year from 1992 to 2050. Fertility, life expectancy, and net immigration statistics were also produced with the same degree of detail. Most of these data are not published, but all of them are available from the Bureau of the Census, either in paper copy or in machine-readable form. Further information may be obtained by writing to the Chief, Population Division, Bureau of the Census, Washington, DC 20233-3400.

The following Current Population Reports in the P-25 series contain population information related to that shown in this report. We have discontinued the presentation of historical data series in projections reports. For

your convenience, we list prior reports that provide historical data. The earlier projection reports also have historical data for derivative data such as fertility rates and life expectancy.
